Version	1.2.0

**Date** 2005-4

Title Statistical Analysis of Haplotypes with Traits and Covariates when Linkage Phase is Ambiguous

Author Jason P. Sinnwell and Daniel J. Schaid

Maintainer Jason P. Sinnwell <sinnwell.jason@mayo.edu>

**Description** Haplo Stats is a suite of S-PLUS/R routines for the analysis of indirectly measured haplotypes. The statistical methods assume that all subjects are unrelated and that haplotypes are ambiguous (due to unknown linkage phase of the genetic markers). The genetic markers are assumed to be codominant (i.e., one-to-one correspondence between their genotypes and their phenotypes), and so we refer to the measurements of genetic markers as genotypes. The main functions in Haplo Stats are: haplo.em, haplo.glm and haplo.score.

Ginv 3

Ginv

Compute Generalized Inverse of Input Matrix

### **Description**

Singular value decomposition (svd) is used to compute a generalized inverse of input matrix.

### Usage

Ginv(x)

### Arguments

х

A matrix.

#### **Details**

The svd function uses the LAPACK library standard to compute the singular values of the input matrix, and the rank of the matrix is determined by the number of singular values that are at least as large as  $\max(\text{svd})^*\text{eps}$ , where eps is a small value (currently eps = .000001). For S-PLUS, the Matrix library is required.

#### Value

List with components:

Ginv Generalized inverse of x.

rank Rank of matrix x.

### Side Effects

4 allele.recode

allele.recode

Recode allele values to integer ranks

# Description

Genotypes for subjects represented by a pair of vectors, with the vectors containing allele values (either numeric, factor, or character), are recoded to the rank order of allele values.

### Usage

```
allele.recode(a1, a2, miss.val=NA)
```

#### **Arguments**

a1 Vector of "first" alleles.a2 Vector of "second" alleles.

miss.val Vector of missing value codes for alleles.

### **Details**

If alleles are numeric, they are recoded to the rank order of the alleles. If the alleles are factor or character, they are recoded to interger values that correspond to the indices of the sorted values of the unique alleles, but sorted as character values.

### Value

List with components:

a1 Vector of recoded "first" alleles.a2 Recode of recoded "second" alleles.allele.label Vector of labels for unique alleles.

6 geno.count.pairs

geno.count.pairs Counts of Total Haplotype Pairs Produced by Genotypes

#### **Description**

Provide a count of all possible haplotype pairs for each subject, according to the phenotypes in the rows of the geno matrix. The count for each row includes the count for complete phenotypes, as well as possible haplotype pairs for phenotypes where there are missing alleles at any of the loci.

#### Usage

```
geno.count.pairs(geno)
```

#### **Arguments**

geno

Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then geno has 2\*K columns. Rows represent all observed alleles for each subject, their phenotype.

#### **Details**

When a subject has no missing alleles, and has h heterozygous sites, there are 2\*\*(h-1) haplotype pairs that are possible ('\*\*'=power). For loci with missing alleles, we consider all possible pairs of alleles at those loci. Suppose that there are M loci with missing alleles, and let the vector V have values 1 or 0 according to whether these loci are imputed to be heterozygous or homozygous, respectively. The length of V is M. The total number of possible states of V is 2\*\*M. Suppose that the vector W, also of length M, provides a count of the number of possible heterozygous/homozygous states at the loci with missing data. For example, if one allele is missing, and there are K possible alleles at that locus, then there can be one homozygous and (K-1) heterozygous genotypes. If two alleles are missing, there can be K homozygous and K(K-1)/2 heterozygous genotypes. Suppose the function H(h+V) counts the total number of heterozygous sites among the loci without missing data (of which h are heterozygous) and the imputed loci (represented by the vector V). Then, the total number of possible pairs of haplotypes can be respresented as SUM(W\*H(h+V)), where the sum is over all possible values for the vector V.

#### Value

Vector where each element gives a count of the number haplotype pairs that are consistent with a subject's phenotype, where a phenotype may include 0, 1, or 2 missing alleles at any locus.

### **Examples**

```
setupData(hla.demo)
geno <- hla.demo[,c(17,18,21:24)]
geno <- geno.recode(geno)$grec
count.geno <- geno.count.pairs(geno)
print(count.geno)</pre>
```

geno.recode

Recode Genotypes

#### **Description**

For all loci as pairs of columns in a matrix, recode alleles

### Usage

```
geno.recode(geno, miss.val=0)
```

### **Arguments**

geno

Matrix of alleles, such that each locus has a pair of adjacent columns of alleles. If

there are K loci, then ncol(geno) = 2\*K. Rows represent alleles for each subject.

miss.val

Vector of codes for missing values of alleles.

#### **Details**

#### Value

List with components:

grec

Matrix of recoded alleles - see allele.recode

alist

List of allele labels. For K loci, there are K components in the list, and the  $kth\,$ 

component is a vector of sorted unique allele labels for the kth locus.

haplo.cc	Haplotype Association Analysis in a Case-Control design	

# Description

Combine results from haplo.score, haplo.group, and haplo.glm for case-control study designs. Analyze the association between the binary (case-control) trait and the haplotypes relevant to the unrelated individuals' genotypes.

#### Usage

### **Arguments**

У	Vector of trait values, must be 1 for cases and 0 for controls.
geno	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then $ncol(geno) = 2*K$ . Rows represent alleles for each subject.
haplo.min.co	unt
	The minimum number of expected counts for a haplotype in the sample based on estimated frequencies.
ci.prob	Probability level for confidence interval on the Odds Ratios of each haplotype to span the true value.
locus.label	Vector of labels for loci, of length K (see definition of geno matrix)
miss.val	Vector of codes for missing values of alleles
simulate	Logical: if [F]alse, no empirical p-values are computed; if [T]rue, simulations are performed within haplo.score. Specific simulation parameters can be controlled in the sim.control parameter list.
sim.control	A list of control parameters to determine how simulations are performed for simulated p-values. The list is created by the function score.sim.control and the default values of this function can be changed as desired. See score.sim.control for details.
control	A list of control parameters for managing the execution of haplo.cc. The list is created by the function haplo.glm.control, which also manages control parameters for the execution of haplo.em.

#### **Details**

All function calls within haplo.cc are for the analysis of association between haplotypes and the case-control status (binomial trait). No additional covariates may be modeled with this function. Odd Ratios are in reference to the baseline haplotype. Odds Ratios will change if a different baseline is chosen using haplo.glm.control.

10 haplo.cc

#### Value

A list including the haplo.score object (score.lst), vector of subject counts by case and control group (group.count), haplo.glm object (fit.lst), confidence interval probability (ci.prob), and a data frame (cc.df) with the following components:

haplotypes	The first K columns contain the haplotypes used in the analysis.
Hap-Score	Score statistic for association of haplotype with the binary trait.
p-val	P-value for the haplotype score statistic, based on a chi-square distribution with 1 degree of freedom.
sim.p.val	Vector of p-values for score.haplo, based on simulations in haplo.score (omitted when simulations not performed). P-value of score.global based on simulations (set equal to NA when simulate=F).
pool.hf	Estimated haplotype frequency for cases and controls pooled together.
control.hf	Estimated haplotype frequency for control group subjects.
case.hf	Estimated haplotype frequency for case group subjects.
glm.eff	The haplo.glm function modeled the haplotype effects as: baseline (Base), additive haplotype effect (Eff), or rare haplotypes pooled into a single group (R).
OR.lower	Lower limit of the Odds Ratio Confidence Interval.
OR	Odds Ratio based on haplo.glm model estimated coefficient for the haplotype.
OR.upper	Upper limit of the Odds Ratio Confidence Interval.

12 haplo.em

haplo.em	EM Computation of Haplotype Probabilities, with Progressive Inser-
	tion of Loci

#### **Description**

For genetic marker phenotypes measured on unrelated subjects, with linkage phase unknown, compute maximum likelihood estimates of haplotype probabilities. Because linkage phase is unknown, there may be more than one pair of haplotypes that are consistent with the oberved marker phenotypes, so posterior probabilities of pairs of haplotypes for each subject are also computed. Unlike the usual EM which attempts to enumerate all possible pairs of haplotypes before iterating over the EM steps, this "progressive insertion" algorithm progressively inserts batches of loci into haplotypes of growing lengths, runs the EM steps, trims off pairs of haplotypes per subject when the posterior probability of the pair is below a specified threshold, and then continues these insertion, EM, and trimming steps until all loci are inserted into the haplotype. The user can choose the batch size. If the batch size is chosen to be all loci, and the threshold for trimming is set to 0, then this algorithm reduces to the usual EM algorithm.

#### Usage

#### **Arguments**

geno matrix of alleles, such that each locus has a pair of adjacent columns of alleles,

and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then ncol(geno) = 2\*K. Rows represent the alleles for each

subject.

locus.label vector of labels for loci.

miss.val vector of values that represent missing alleles in geno.

weight weights for observations (rows of geno matrix).

control list of control parameters. The default is constructed by the function haplo.em.control.

The default behavior of this function results in the following parameter settings: loci.insert.order=1:n.loci, insert.batch.size=min(4,n.loci), min.posterior= 0.0001, tol=0.00001, max.iter=500, random.start=0 (no random start), iseed=NULL (no saved seed to start random start), verbose=0 (no printout during EM itera-

tions). See haplo.em.control for more details.

#### **Details**

#### Value

list with components:

converge indicator of convergence of the EM algorithm (1 = converge, 0 = failed).

1nlike value of lnlike at last EM iteration (maximum lnlike if converged).

haplo.em 13

lr	likelihood ratio statistic to test the final lnlike against the lnlike that assumes complete linkage equilibrium among all loci (i.e., haplotype frequencies are products of allele frequencies).
df.lr	degrees of freedom for likelihood ratio statistic. The df for the unconstrained final model is the number of non-zero haplotype frequencies minus 1, and the df for the null model of complete linkage equilibrium is the sum, over all loci, of (number of alleles - 1). The df for the lr statistic is df[unconstrained] - df[null]. This can result in negative df, if many haplotypes are estimated to have zero frequency, or if a large amount of trimming occurs, when using large values of min.posterior in the list of control parameters.
hap.prob	vector of mle's of haplotype probabilities. The ith element of hap.prob corresponds to the ith row of haplotype.
locus.label	vector of labels for loci, of length K (see definition of input values).
subj.id	vector of id's for subjects used in the analysis, based on row number of input geno matrix. If subjects are removed, then their id will be missing from subj.id.
rows.rem	now defunct, but set equal to a vector of length 0, to be compatible with other functions that check for rows.rem.
indx.subj	vector for row index of subjects after expanding to all possible pairs of haplo- types for each person. If indx.subj=i, then i is the ith row of geno. If the ith subject has n possible pairs of haplotypes that correspond to their marker geno- type, then i is repeated n times.
nreps	vector for the count of haplotype pairs that map to each subject's marker genotypes.
max.pairs	vector of maximum number of pairs of haplotypes per subject that are consistent with their marker data in the matrix geno. The length of max.pairs = nrow(geno). This vector is computed by geno.count.pairs.
haplcode	vector of codes for each subject's first haplotype. The values in hap1code are the row numbers of the unique haplotypes in the returned matrix haplotype.
hap2code	similar to hap1code, but for each subject's second haplotype.
post	vector of posterior probabilities of pairs of haplotypes for a person, given their marker phenotypes.
haplotype	matrix of unique haplotypes. Each row represents a unique haplotype, and the number of columns is the number of loci.
control	list of control parameters for algorithm. See haplo.em.control

# **Side Effects**

# References

The basis of this progressive insertion algorithm is from the sofware snphap by David Clayton. Although some of the features and control parameters of this S-PLUS version are modeled after snphap, there are substantial differences, such as extension to allow for more than two alleles per locus, and some other nuances on how the alogrithm is implemented.

# warning: output will not exactly match
print.haplo.em(save.em.keep)
```

haplo.em.control

Create the Control Parameters for the EM Computation of Haplotype Probabilities, with Progressive Insertion of Loci

#### **Description**

Create a list of parameters that control the EM algorithm for estimating haplotype frequencies, based on progressive insertion of loci. Non-default parameters for the EM algorithm can be set as parameters passed to haplo.em.control.

### Usage

```
haplo.em.control(loci.insert.order=NULL, insert.batch.size = 6,
                             min.posterior = 1e-07, tol = 1e-05,
                             max.iter=5000, random.start=0, n.try = 10,
                             iseed=NULL, max.haps.limit = 2e6, verbose=0)
```

#### **Arguments**

tol

loci.insert.order

Numeric vector with specific order to insert the loci. If this value is NULL, the insert oder will be in sequential order (1, 2, ..., No. Loci).

insert.batch.size

Number of loci to be inserted in a single batch.

min.posterior

Minimum posterior probability of a haplotype pair, conditional on observed marker genotypes. Posteriors below this minimum value will have their pair of haplotypes "trimmed" off the list of possible pairs.

If the change in log-likelihood value between EM steps is less than the tolerance

(tol), it has converged.

Maximum number of iterations allowed for the EM algorithm before it stops and max.iter

prints an error. If the error is printed, double max.iter.

random.start

If random.start = 0, then the inititial starting values of the posteriors for the first EM attempt will be based on assuming equal posterior probabilities (conditional on genotypes). If random.start = 1, then the initial starting values of the first EM attempt will be based on assuming a uniform distribution for the initial posterior probabilities.

haplo.em.fitter 15

n.try

Number of times to try to maximize the lnlike by the EM algorithm. The first try uses, as initial starting values for the posteriors, either equal values or uniform random variables, as determined by random.start. All subsequent tries will use random uniform values as initial starting values for the posterior probabilities.

An integer or a saved copy of .Random.seed. This allows simulations to be

reproduced by using the same initial seed.

max.haps.limit

The maximum number of haplotypes for which memory is allocated.

verbose Logical, if [T]rue, print procedural messages to the screen. If [F]alse, do not

print any messages.

#### **Details**

The default is to use n.try = 10. If this takes too much time, it may be worthwhile to decrease n.try. Other tips for computing haplotype frequencies for a large number of loci, particularly if some have many alleles, is to decrease the batch size (insert.batch.size), increase the memory (max.haps.limit).

#### Value

A list of the parameters passed to the function.

#### **Side Effects**

#### References

#### See Also

```
haplo.em, haplo.score
```

### **Examples**

haplo.enum 17

haplo.enum	Enumerate all possible pairs of haplotypes that are consistent with a set of un-phased multilocus markers

### **Description**

Given subject un-phased genotype hmat, enumerate all possible pairs of haplotypes, and return enumerated pairs in matrices h1 and h2.

### Usage

```
haplo.enum(hmat)
```

#### **Arguments**

hmat

A genotype vector of length 2\*K (K = number of loci). When used in haplo.em, it is a single row of a genotype matrix.

### **Details**

For a pair of haplotypes, if there are H sites that are heterozygous, then there are 2 raised to (H-1) possible pairs to enumerate. To achieve this, the algorithm moves across the loci that are heterozygous (after the 1st heterozygous locus), flipping alleles at heterozygous locations to enumerate all possible pairs of haplotpes, and appending results as rows of the output matrices h1, and h2.

#### Value

List with components:

h1	A matrix of enumerated hap	lotypes. If there are	N enumerations, h1 will have
----	----------------------------	-----------------------	------------------------------

dimension N x K.

h2 Similar to h1, a matrix of enumerated haplotypes for the second members of

the pairs of haplotypes. Haplotype pairs in h1 and h2 match by the same row

number.

# **Side Effects**

# See Also

haplo.em

haplo.glm

GLM Regression of Trait on Ambiguous Haplotypes

#### **Description**

Perform glm regression of a trait on haplotype effects, allowing for ambiguous haplotypes. This method performs an iterative two-step EM, with the posterior probabilities of pairs of haplotypes per subject used as weights to update the regression coefficients, and the regression coefficients used to update the posterior probabilities.

### Usage

```
haplo.glm(formula=formula(data), family=gaussian, data=sys.parent(),
    weights, na.action="na.geno.keep", start=eta, miss.val=c(0,NA),
    locus.label=NA, allele.lev=NULL, control=haplo.glm.control(),
    method="glm.fit", model=FALSE, x=FALSE, y=TRUE,
    contrasts=NULL, ...)
```

#### **Arguments**

formula

a formula expression as for other regression models, of the form response predictors. For details, see the documentation for lm and formula.

family

a family object. This is a list of expressions for defining the link, variance function, initialization values, and iterative weights for the generalized linear model. Supported families are: gaussian, binomial, poisson. Currently, only the logit link is implemented for binimial.

data

a data frame in which to interpret the variables occurring in the formula. A CRITICAL element of the data frame is the matrix of genotypes, denoted here as "geno", although an informative name should be used in practice. This geno matrix is actually a matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then ncol(geno) = 2\*K. Rows represent the alleles for each subject. It is also CRITICAL that this matrix is defined as a model.matrix, in order to keep the columns of the matrix packaged together into the single matrix object. If geno is a matrix of alleles, then before adding it to the data frame, use the following command to convert it to a model.matrix: oldClass(geno) <- "model.matrix". If geno is a data.frame of alleles, you must first convert geno to a matrix, using geno <- as.matrix(geno), and then convert it to a model.matrix.

weights

the weights for observations (rows of the data frame). By default, all observations are weighted equally.

na.action

a function to filter missing data. This is applied to the model.frame. The default value of na.action=na.geno.keep will keep observations with missing alleles, but exclude observations missing any other data (e.g., response variable, other covariates, weight). The EM algorithm for ambiguous haplotypes accounts for missing alleles. Similar to the usual glm, na.fail creates an error if any missing values are found, and a third possible alternative is na.exclude, which deletes observations that contain one or more missing values for any data, including alleles.

start a vector of initial values on the scale of the linear predictor.

miss.val vector of values that represent missing alleles in geno matrix.

locus.label vector of labels for loci.

allele.lev This argument is optional ONLY for S-PLUS, but is REQUIRED for R. This is

a list of vectors, each vector giving the labels of alleles for each locus. The list is made an attribute of geno<-setupGeno(geno). This is required to account for the differences in which S-PLUS and R handle character data (allele labels) in a

model.frame. See its use in the example below.

control list of control parameters. The default is constructed by the function haplo.glm.control.

The items in this list control the regression modeling of the haplotypes (e.g., additive, dominant, recessive effects of haplotypes; which haplotype is chosen as the baseline for regression; how to handle rare haplotypes; control of the glm function - maximum number of iterations), and the EM algorithm for estimating

initial haplotype frequencies. See haplo.glm.control for details.

method currently, glm.fit is the only method allowed.

model if model=TRUE, the model.frame is returned.

x a logical flag. If x=TRUE, the model.matrix is returned. By default, x=FALSE.

y a logical flag. The default value of y=TRUE causes the response variable to be

returned.

contrasts currently, contrasts is ignnored (so NULL, the default value, is always used).

... potential other arguments that may be passed - currently ignored.

#### **Details**

#### Value

An object of class "haplo.glm" is returned. The output object from haplo.glm has all the components of a glm object, with a few more. It is important to note that some of the returned components correpond to the "expanded" version of the data. This means that each observation is expanded into the number of terms in the observation's posterior distribution of haplotype pairs, given the marker data. For example, when fitting the response y on haplotype effects, the value of y[i], for the ith observation, is replicated m[i] times, where m[i] is the number of pairs of haplotypes consistent with the observed marker data. The returned components that are expanded are indicated below by [expanded] in the definition of the component. These expanded components may need to be collapsed, depending on the user's objectives. For example, when considering the influence of an observation, it may make sense to examine the expanded residuals for a single observation, perhaps plotted against the haplotypes for that observation. In contrast, it would not be sensible to plot all residuals against non-genetic covaraites, without first collapsing the expanded residuals for each observation. To collapse, one can use the average residual per observation, weighted according to the posterior probabilities. The appropriate weight can be computed as wt = fit\subseteq fit\subseteq weight.expanded \* fit\$haplo.post.info\$post. Then, the weighted average can be calculated as tapply(fit\$residuals \* wt, fit\$haplo.post.info\$indx, sum).

coefficients of the linear.predictors, which multiply the columns of the model matrix. The names of the coefficients are the names of the columns of the model matrix. For haplotype coefficients, the names are the concatentation of name of the geno matrix with a haplotype number. The haplotype number corresponds to

the index of the haplotype. The default print will show the coefficients with haplotype number, along with the alleles that define the haplotype, and the estimated haplotype frequency. If the model is over-determined there will be missing values in the coefficients corresponding to inestimable coefficients.

residuals [expanded] residuals from the final weighted least squares fit; also known as

working residuals, these are typically not interpretable without rescaling by the

weights (see glm.object).

fitted.values

[expanded] fitted mean values, obtained by transforming linear.predictors using

the inverse link function (see glm.object).

effects [expaded] orthogonal, single-degree-of-freedom effects (see lm.object).

R the triangular factor of the decomposition (see lm.object).

rank the computed rank (number of linearly independent columns in the model ma-

trix), which is the model degrees of freedom - see lm.object.

assign the list of assignments of coefficients (and effects) to the terms in the model (see

lm.object).

df.residual [expanded] number of degrees of freedom for residuals, corresponding to the

expanded data.

weights.expanded

[expanded] input weights after expanding according to the number of pairs of

haplotypes consistent with an observation's marker genotype data.

family a 3 element character vector giving the name of the family, the link and the

variance function; mainly for printing purposes.

linear.predictors

[expanded] linear fit, given by the product of the model matrix and the coeffi-

cients; also the fitted values from the final weighted least squares fit.

deviance [expanded] up to a constant, minus twice the maximized log-likelihood. Similar

to the residual sum of squares.

null.deviance

the deviance corresponding to the model with no predictors.

call an image of the call that produced the object, but with the arguments all named

and with the actual formula included as the formula argument.

iter the number of IRLS iterations used to compute the estimates, for the last step of

the EM fit of coefficients.

y [expanded] response, if y=T.

contrasts a list containing sufficient information to construct the contrasts used to fit any

factors occurring in the model (see lm.object).

lnlike log-likelihood of the fitted model.

lnlike.null log-likelihood of the null model that has only an intercept.

lrt likelihood ratio test statistic to test whether all coefficients (except intercept)

are zero: 2\*(lnlike - lnlike.null)

terms an object of mode expression and class term summarizing the formula, but not

complete for the final model. Because this does not represent expansion of the design matrix for the haplotypes, it is typically not of direct relevance to users.

control list of all control parameters

haplo.unique the data.frame of unique haplotypes

the index of the haplotype used as the base-line for the regression model. To see the actual haplotype definition, use the following: fit\$haplo.unique[fit\$haplo.base,], where fit is the saved haplo.glm object (e.g., fit <- haplo.glm(y geno, ...)).

the final estimates of haplotype frequencies, after completing EM steps of updating haplotype frequencies and regression coefficients. The length of haplo.freq is the number of rows of haplo.unique, and the order of haplo.freq is the same as that for the rows of haplo.unique. So, the frequencies of the unique haplotypes can be viewed as cbind(fit\$haplo.unique, fit\$haplo.freq).

haplo.freq.init

the initial estimates of haplotype frequencies, based on the EM algorithm for estimating haplotype frequencies, ingnoring the trait. These can be compared with haplo.freq, to see the impact of using the regression model to update the haplotype frequencies.

converge.em T/F whether the initial EM algorithm for estimating haplo.freq.init converged.

haplo.common the indices of the haplotypes determined to be "common" enough to estimate their corresponding regression coefficients.

haplo.rare the indices of all the haplotypes determined to be too rare to estimate their specific regression coefficients.

haplo.rare.term

T/F whether the "rare" term is included in the haplotype regression model.

haplo.names the names of the coefficients that represent haplotype effects.

haplo.post.info

a data.frame of information regarding the posterior probabilites. The columns of this data.frame are: indx (the index of the input obsevation; if the ith observation is repeated m times, then indx will show m replicates of i; hence, indx will correspond to the "expanded" observations); hap1 and hap2 (the indices of the haplotypes; if hap1=j and hap2=k, then the two haplotypes in terms of alleles are fit\$haplo.unique[j,] and fit\$haplo.unique[k,]); post.init (the initial posterior probability, based on haplo.freq.init); post (the final posterior probability, based on haplo.freq).

x the model matrix, with [expanded] rows, if x=T.

info the observed information matrix, based on Louis' formula. The upper left submatrix is for the regression coefficient, the lower right submatrix for the haplotype frequencies, and the remaining is the information between regression coef-

ficients and haplotype frequencies.

var . mat the variance-covariance matrix of regression coefficients and haplotype frequen-

cies, based on the inverse of info. Upper left submatrix is for regression coeffi-

cients, lower right submatrix for haplotype frequencies.

haplo.elim the indices of the haplotypes eliminated from the info and var.mat matrices be-

cause their frequencies are less than haplo.min.info (the minimum haplotype frequency required for computation of the information matrix - see haplo.glm.control)

rank.info rank of information (info) matrix.

               "na.geno.keep", allele.lev=attributes(geno)$unique.alleles,
               data=my.data, locus.label=label,
               control = haplo.glm.control(haplo.freq.min=0.02))
 fit.gaus
```

haplo.glm.control Create list of control parameters for haplo.glm

#### **Description**

Create a list of control pararameters for haplo.glm. If no parameters are passed to this function, then all default values are used.

#### Usage

haplo.glm.control 23

#### **Arguments**

haplo.effect

the "effect" of a haplotypes, which determines the covariate (x) coding of haplotypes. Valid options are "additive" (causing x=0, 1, or 2, the count of a particular haplotype), "dominant" (causing x=1 if heterozygous or homozygous carrier of a particular haplotype; x=0 otherwise), and "recessive" (causing x=1 if homozygous for a particular haplotype; x=0 otherwise).

haplo.base

the index for the haplotype to be used as the base-line for regression. By default, haplo.base=NULL, so that the most frequent haplotype is chosen as the base-line.

haplo.min.count

The minimum number of expected counts for a haplotype from the sample to be included in the model. The count is based on estimated haplotype frequencies. Suggested minimum is 5.

haplo.freq.min

the minimum haplotype frequency for a haplotype to be included in the regression model as its own effect. The haplotype frequency is based on the EM algorithm that estimates haplotype frequencies independent of trait.

sum.rare.min

the sum of the "rare" haplotype frequencies must be larger than sum.rare.min in order for the pool of rare haplotypes to be included in the regression model as a separate term. If this condition is not met, then the rare haplotypes are pooled with the base-line haplotype (see keep.rare.haplo below).

haplo.min.info

the minimum haplotype frequency for determining the contribution of a haplotype to the observed information matrix. Haplotypes with less frequency are dropped from the observed information matrix. The haplotype frequency is that from the final EM that iteratively updates haplotype frequencies and regression coefficients.

keep.rare.haplo

TRUE/FALSE to determine if the pool of rare haplotype should be kept as a separate term in the regression model (when keep.rare.haplo=TRUE), or pooled with the base-line haplotype (when keep.rare.haplo=FALSE).

glm.c list of control parameters for the usual glm.control (see glm.control).

em.c list of control parameters for the EM algorithm to estimate haplotype frequencies, independent of trait (see haplo.em.control).

haplo.group

Frequencies for Haplotypes by Grouping Variable

### **Description**

Calculate maximum likelihood estimates of haplotype probabilities for the entire dataset and separately for each subset defined by the levels of a group variable. Only autosomal loci are considered.

### Usage

### Arguments

group	Group can be of logical, numeric, character, or factor class type.	
geno	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then geno has 2*K columns. Rows represent all observed alleles for each subject.	
locus.label	Vector of labels for loci, of length K (see definition of geno matrix).	
miss.val	Vector of codes for allele missing values.	
control	list of control parameters for haplo.em (see haplo.em.control).	

### **Details**

Haplo.em is used to compute the maximum likelihood estimates of the haplotype frequencies for the total sample, then for each of the groups separately.

### Value

	A list as an object of the haplo.group class. The three elements of the list are described below.
group.df	A data frame with the columns described as followshaplotype: Names for the K columns for the K alleles in the haplotypestotal: Estimated frequencies for haplotypes from the total samplegroup.name.i: Estimated haplotype frequencies for the haplotype if it occurs in the group referenced by 'i'. Frequency is NA if it doesn't occur for the group. The column name is the actual variable name joined with the ith level of that variable.
group.count	Vector containing the number of subjects for each level of the grouping variable.
n.loci	Number of loci occuring in the geno matrix.

### **Side Effects**

haplo.hash 25

setupData(hla.demo)
geno <- as.matrix(hla.demo[,c(17,18,21:24)])

# remove any subjects with missing alleles for faster examples,
# but you may keep them in practice
keep <- !apply(is.na(geno) | geno==0, 1, any)
hla.demo <- hla.demo[keep,]
geno <- geno[keep,]
attach(hla.demo)

y.ord <- as.numeric(resp.cat)
y.bin <-ifelse(y.ord==1,1,0)
group.bin <- haplo.group(y.bin, geno, miss.val=0)
print.haplo.group(group.bin)</pre>
```

haplo.hash

Integer Rank Codes for Haplotypes

### **Description**

Create a vector of integer codes for the input matrix of haplotypes. The haplotypes in the input matrix are converted to character strings, and if there are C unique strings, the integer codes for the haplotypes will be 1, 2, ..., C.

#### Usage

```
haplo.hash(hap)
```

## Arguments

hap

A matrix of haplotypes. If there are N haplotypes for K loci, hap have dimensions N x K.

#### **Details**

The alleles that make up each row in hap are pasted together as character strings, and the unique strings are sorted so that the rank order of the sorted strings is used as the integer code for the unique haplotypes.

26 haplo.model.frame

### Value

List with elements:

hash Vector of integer codes for the input data (hap). The value of hash is the row

number of the unique haplotypes given in the returned matrix hap.mtx.

hap.mtx Matrix of unique haplotypes.

#### **Examples**

haplo.scan

Search for a trait-locus by sliding a fixed-width window over each marker locus and scanning all possible haplotype lengths within the window

### **Description**

Search for haplotypes that have the strongest association with a binary trait (typically case/control status) by sliding a fixed-width window over each marker locus and scanning all possible haplotype lengths within the window. For each haplotype length, a score statistic is computed to compare the set of haplotypes with a given length between cases versus controls. The locus-specific score statistic is the maximum score statistic calculated on loci containing that locus. The maximum score statistic over all haplotype lengths within all possible windows is used for a global test for association. Permutations of the trait are used to compute p-values.

# Usage

### Arguments

У	Vector of binary trait values, must be 1 for cases and 0 for controls.
geno	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then $ncol(geno) = 2*K$ . Rows represent alleles for each subject.
width	Width of sliding the window
miss.val	Vector of codes for missing values of alleles
em.control	A list of control parameters to determine how to perform the EM algorithm for estimating haplotype frequencies when phase is unknown. The list is created by the function haplo.em.control - see this function for more details.
sim.control	A list of control parameters to determine how simulations are performed for simulated p-values. The list is created by the function score.sim.control and the default values of this function can be changed as desired. See score.sim.control for details.

28 haplo.scan

#### **Details**

Search for a region for which the haplotypes have the strongest association with a binary trait by sliding a window of fixed width over each marker locus, and considering all haplotype lengths within each window. To acount for unknown linkage phase, the function haplo.em is called prior to scanning, to create a list of haplotype pairs and posterior probabilities. To illustrate the scanning, consider a 10-locus dataset. When placing a window of width 3 over locus 5, the possible haplotype lengths that contain locus 5 are three (loci 3-4-5, 4-5-6, and 5-6-7), two (loci 4-5, and 5-6) and one (locus 5). For each of these loci subsets a score statistic is computed, which is based on the difference between the mean vector of haplotype counts for cases and that for controls. The maximum of these score statistics, over all possible haplotype lengths within a window, is the locus-specific test statistic. The global test statistic is the maximum over all computed score statistics. To compute p-values, the case/control status is randomly permuted. Simulations are performed until precision criteria are met for all p-values; the criteria are controlled by score.sim.control.

#### Value

A list that has class haplo.scan, which contains the following items:

call	The call to haplo.scan
scan.df	A data frame containing the maximum test statistic for each window around each locus, and its simulated p-value.
max.loc	The loci (locus) which contain(s) the maximum observed test statistic over all haplotype lengths and all windows.
globalp	A p-value for the significance of the global maximum statistic.
nsim	Number of simulations performed

#### Side Effects

For datasets with many estimated haplotypes, the run-time can be very long.

haplo.score 31

haplo.score	Score Statistics for Association of Traits with Haplotypes	

# Description

Compute score statistics to evaluate the association of a trait with haplotypes, when linkage phase is unknown and diploid marker phenotypes are observed among unrelated subjects. For now, only autosomal loci are considered.

# Usage

### Arguments

У	Vector of trait values. For trait.type = "binomial", y must have values of 1 for event, $0$ for no event.
geno	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then $ncol(geno) = 2*K$ . Rows represent alleles for each subject.
trait.type	Character string defining type of trait, with values of "gaussian", "binomial", "poisson", "ordinal".
offset	Vector of offset when trait.type = "poisson"
x.adj	Matrix of non-genetic covariates used to adjust the score statistics. Note that intercept should not be included, as it will be added in this function.
skip.haplo	Skip score statistics for haplotypes with frequencies $<$ skip.haplo. The default is for an expected count of 5 out of the $2*N$ haplotype occurrences.
locus.label	Vector of labels for loci, of length K (see definition of geno matrix)
miss.val	Vector of codes for missing values of alleles
simulate	Logical: if [F]alse, no empirical p-values are computed; if [T]rue, simulations are performed. Specific simulation parameters can be controlled in the sim.control parameter list.
sim.control	A list of control parameters to determine how simulations are performed for simulated p-values. The list is created by the function score.sim.control and the default values of this function can be changed as desired. See score.sim.control for details.
em.control	A list of control parameters to determine how to perform the EM algorithm for estimating haplotype frequencies when phase is unknown. The list is created by the function haplo.em.control - see this function for more details.

32 haplo.score

#### **Details**

Compute the maximum likelihood estimates of the haplotype frequencies and the posterior probabilities of the pairs of haplotypes for each subject using an EM algorithm. The algorithm begins with haplotypes from a subset of the loci and progressively discards those with low frequency before inserting more loci. The process is repeated until haplotypes for all loci are established. The posterior probabilities are used to compute the score statistics for the association of (ambiguous) haplotypes with traits. The glm function is used to compute residuals of the regression of the trait on the non-genetic covariates.

#### Value

List with the following components:

score.global Global statistic to test association of trait with haplotypes that have frequencies >= skip.haplo.

df Degrees of freedom for score.global.

score.global.p

P-value of score.global based on chi-square distribution, with degrees of freedom equal to df.

score.global.p.sim

P-value of score.global based on simulations (set equal to NA when simulate=F).

score.haplo Vector of score statistics for individual haplotypes that have frequencies >= skip.haplo.

score.haplo.p

Vector of p-values for score.haplo, based on a chi-square distribution with 1 df.

score.haplo.p.sim

Vector of p-values for score.haplo, based on simulations (set equal to NA when simulate=F).

score.max.p.sim

Simulated p-value indicating for simulations the number of times a maximum score.haplo value exceeds the maximum score.haplo from the original data (equal to NA when simulate=F).

haplotype Matrix of hapoltypes analyzed. The ith row of haplotype corresponds to the ith item of score.haplo, score.haplo.p, and score.haplo.p.sim.

hap.prob Vector of haplotype probabilies, corresponding to the haplotypes in the matrix haplotype.

locus.label Vector of labels for loci, of length K (same as input argument).

Same as function input parameter. If [T]rue, simulation results are included in the haplo.score object.

n.val.global Vector containing the number of valid simulations used in the global score statistic simulation. The number of valid simulations can be less than the number of simulations requested (by sim.control) if simulated data sets produce unstable variances of the score statistics.

n.val.haplo Vector containing the number of valid simulations used in the p-value simulations for maximum-score statistic and scores for the individual haplotypes.

haplo.score.glm

haplo.score.glm Compute haplotype score statistics for GLM

### **Description**

This function is used by haplo.score when analyzing traits by a GLM score.

### Usage

```
haplo.score.glm(y, mu, a, v, x.adj, nreps, x.post, post, x)
```

### **Arguments**

У	Vector of trait values.
mu	Expected value of y.
a	scale parameter
v	v= b"/a for a GLM.
x.adj	Matrix of non-genetic covariates used to adjust the score statistics. Note that intercept should be included in this matrix.
nreps	Vector for the count of haplotype pairs that map to each subject's marker genotypes (see haplo.em).
x.post	Matrix for posterior mean of x per subject.
post	Vector of posterior probabilities of pairs of haplotypes for a person, given thier marker phenotypes (see haplo.em).
х	Matrix of scores for enumerated haplotypes for each subject, with elements 0, 1, 2 (counts of specific haplotypes).
None.	

#### **Details**

Using posterior probabilities of pairs of haplotypes, the "design" matrix for the haplotype effects, and the GLM residuals, compute the score vector and its variance matrix, adjusted for the non-genetic covariates.

# Value

List with components:

u.scorev.scoreVector of scores for the chosen haplotypesv.scoreCovariance matrix for u.score

haplo.score

### **Examples**

haplo.score.merge Merge haplo.score And haplo.group Objects

### **Description**

Combine information from returned objects of haplo.score and haplo.group, 'score' and 'group' respectively. 'score' and 'group' are sorted differently and 'score' keeps a subset of all the haplotypes while 'group' has all of them. To combine results from the two objects, merge them by haplotype and sort by score of the haplotype. The merged object includes all haplotypes; i.e. those appearing in 'group', but the print default only shows haplotypes which have a score.

### Usage

```
haplo.score.merge(score, group)
```

#### **Arguments**

group Object returned from haplo.score of class "haplo.score".

Object returned from haplo.group of class "haplo.group".

#### **Details**

Haplo.score returns score statistic and p-value for haplotypes with an overall frequency above the user-specified threshold, skip.haplo. For haplotypes with frequencies below the threshold, the score and p-value will be NA. Overall haplotype frequencies and for sub-groups are estimated by haplo.group.

### Value

Data frame including haplotypes, score-statistics, score p-value, estimated haplotype frequency for all subjects, and haplotype frequency from group subsets.

### **Side Effects**

Warning: The merge will not detect if the group and score objects resulted from different subject phenotypes selected by memory-usage parameters, rm.geno.na and enum.limit. Users must use the same values for these parameters in haplo.score and haplo.group so the merged objects are consistent.

#### See Also

```
haplo.score, haplo.group
```

36 haplo.score.podds

#### **Examples**

```
setupData(hla.demo)
geno <- as.matrix(hla.demo[,c(17,18,21:24)])
keep <- !apply(is.na(geno) | geno==0, 1, any)
hla.demo <- hla.demo[keep,]
geno <- geno[keep,]
attach(hla.demo)
y.ord <- as.numeric(resp.cat)
y.bin <-ifelse(y.ord==1,1,0)

group.bin <- haplo.group(y.bin, geno, miss.val=0)
score.bin <- haplo.score(y.bin, geno, trait.type="binomial")
score.merged <- haplo.score.merge(score.bin, group.bin)</pre>
```

haplo.score.podds Compute Haplotype Score Statistics for Ordinal Traits with Proportional Odds Model

### **Description**

This function is used by haplo.score when analyzing ordinal traits by a proportional odds model score statistic.

#### Usage

```
haplo.score.podds(y, alpha, beta=NA, x.adj=NA, nreps, x.post, post, x)
```

### **Arguments**

У	Vector of ordinal trait values.
alpha	Intercept parameters for ordinal logistic regression model.
beta	Regression parameters for adjusted covariates (x.adj).
x.adj	Matrix of non-genetic covariates used to adjust the score statistics. Note that intercept should NOT be included in this matrix.
nreps	Vector for the count of haplotype pairs that map to each subject's marker genotypes (see haplo.em).
x.post	Matrix for posterior mean of x per subject.
post	Vector of posterior probabilities of pairs of haplotypes for a person, given thier marker phenotypes (see haplo.em).
x	Matrix of scores for enumerated haplotypes for each subject, with elements 0, 1, 2 (counts of specific haplotypes).
None.	

#### **Details**

Using posterior probabilities of pairs of haplotypes, the "design" matrix for the haplotype effects, and the proportional odds model, compute the score vector and its variance matrix, adjusted for the non-genetic covariates.

haplo.score.slide 37

#### Value

List with components:

u.score Vector of scores for the chosen haplotypes

v.score Covariance matrix for u.score

#### **Side Effects**

#### Warning

To analyze an ordinal trait with adjustment for x.adj covariates, the user will need to have Frank Harrell's librarys (Design and Hmisc). However, the unadjusted ordinal trait works fine without these libraries.

haplo.score

### **Examples**

haplo.score.slide Score Statistics for Association of Traits with Haplotypes

### **Description**

Used to identify sub-haplotypes from a group of loci. Run haplo.score on all contiguous subsets of size n.slide from the loci in a genotype matrix (geno). From each call to haplo.score, report the global score statistic p-value. Can also report global and maximum score statistics simulated p-values.

### Usage

38 haplo.score.slide

### **Arguments**

У	Vector of trait values. For trait.type = "binomial", y must have values of 1 for event, 0 for no event.
geno	Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then $ncol(geno) = 2*K$ . Rows represent alleles for each subject.
trait.type	Character string defining type of trait, with values of "gaussian", "binomial", "poisson", "ordinal".
n.slide	Number of loci in each contiguous subset. The first subset is the ordered loci numbered 1 to n.slide, the second subset is 2 through n.slide+1 and so on. If the total number of loci in geno is n.loci, then there are n.loci - n.slide + 1 total subsets.
offset	Vector of offset when trait.type = "poisson"
x.adj	Matrix of non-genetic covariates used to adjust the score statistics. Note that intercept should not be included, as it will be added in this function.
skip.haplo	For haplotypes with frequencies < skip.haplo, categorize them into a common group of rare haplotypes.
locus.label	Vector of labels for loci, of length K (see definition of geno matrix).
miss.val	Vector of codes for missing values of alleles.
simulate	Logical, if [F]alse (default) no empirical p-values are computed. If [T]rue simulations are performed. Specific simulation parameters can be controlled in the sim.control parameter list.
sim.control	A list of control parameters used to perform simulations for simulated p-values in haplo.score. The list is created by the function score.sim.control and the default values of this function can be changed as desired.
em.control	A list of control parameters used to perform the em algorithm for estimating haplotype frequencies when phase is unknown. The list is created by the function haplo.em.control and the default values of this function can be changed as desired.

#### **Details**

Haplo.score.slide is useful for a series of loci where little is known of the association between a trait and haplotypes. Using a range of n.slide values, the region with the strongest association will consistently have low p-values for locus subsets containing the associated haplotypes. The global p-value measures significance of the entire set of haplotypes for the locus subset. Simulated maximum score statistic p-values indicate when one or a few haplotypes are associated with the trait.

### Value

List with the following components:

df	Data frame with start locus, global p-value, simulated global p-value, and simulated maximum-score p-value.
n.loci	Number of loci given in the genotype matrix.
simulate	Same as parameter description above.
n.slide	Same as parameter description above.
locus.label	Same as parameter description above.

haplo.score.slide 39

n.val.haplo Vector containing the number of valid simulations used in the maximum-score statistic p-value simulation. The number of valid simulations can be less than the number of simulations requested (by sim.control) if simulated data sets produce unstable variables of the score statistics.

n.val.global Vector containing the number of valid simulations used in the global score statistic p-value simulation.

40 locator.haplo

hla.demo

HLA Loci and Serologic Response to Measles Vaccination.

### **Description**

Eleven HLA-region loci genotyped for 220 subjects, phase not known. Contains measles vaccination response with covariate data.

### Usage

```
data(hla.demo)
```

#### **Format**

Data Frame with the following columns:

resp Quantitative response to Measles Vaccination

resp.cat Category of response as low, normal, or high; based on 'resp'

male Binary indicator of gender, 1=male, 0=female

age Age of the subject

allele columns 5 - 26 Pairs of columns represent the allele pairs for each subject at the locus.

#### References

locator.haplo

Find Location from Mouse Clicks and Print Haplotypes on Plot

### **Description**

Much like the R/Splus locator function is used to find x-y coordinates on a plot. Find all x-y coordinates that are chosen by the user's mouse clicks. Then print haplotype labels at the chosen positions.

### Usage

```
locator.haplo(obj)
```

loci 41

#### **Arguments**

obj

An object (of class haplo.score) that is returned from haplo.score.

#### **Details**

After plotting the results in obj, as from plot(obj), the function locator.haplo is used to place on the plot the text strings for haplotypes of interest. After the function call (e.g., locator.haplo(obj)), the user can click, with the left mouse button, on as many points in the plot as desired. Then, clicking with the middle mouse button will cause the haplotypes to be printed on the plot. The format of a haplotype is "a:b:c", where a, b, and c are alleles, and the separator ":" is used to separate alleles on a haplotype. The algorithm chooses the closest point that the user clicks on, and prints the haplotype either above the point (for points on the lower-half of the plot) or below the point (for points in the upper-half of the plot).

#### Value

List with the following components:

```
x.coord Vector of x-coordinates.y.coord Vector of y-coordinates.hap.txt Vector of character strings for haplotypes.
```

#### See Also

```
haplo.score
```

#### **Examples**

```
# follow the pseudo-code
# score.out <- haplo.score(y, geno, trait.type = "gaussian")
# plot(score.out)
# locator.haplo(score.out)</pre>
```

loci

Create a group of locus objects from a genotype matrix, assign to 'model.matrix' class.

#### **Description**

The function makes each pair of columns a locus object, which recodes alleles to numeric and saves the original alleles as an attribute of the model.matrix.

### Usage

```
loci(geno, locus.names, chrom.label=NULL, x.linked=FALSE, sex=NULL,
    male.code="M", female.code="F", miss.val=NA, map=NA)
```

42 loci

#### **Arguments**

geno Matrix of alleles, such that each locus has a pair of adjacent columns of alleles,

and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then ncol(geno) = 2\*K. Rows represent alleles for each subject.

locus.names A vector containing the locus name for each locus.

chrom.label Chromosome Label

x.linked A logical value denoting whether the chromosome is X-linked.

sex A vector containing the sex of each individual. If x.linked=F then argument sex

is not required and may be left as the default value of NULL.

male.code The code denoting a male in the sex vector.

female.code The code denoting a female in the sex vector.

miss.val A vector of codes denoting missing values for the allele labels. Note that NA will

always be treated as a missing value, and alleles matching miss.val are assigned NA. Also note that the original missing value code for a specific individual can

not be retrieved from the returned object.

map An optional chromosome map of class "cmap"

#### **Details**

#### Value

An object of class "model.matrix", with all alleles recoded to a numeric value. It contains the following attributes:

locus.names A vector of labels for the loci, of length nloci.

map Will be better defined later.

x.linked A logical value denoting whether the chromosome is X-linked.

unique.alleles

The original allele labels are stored in the 'unique.alleles' attribute. The ith item

of the unique.alleles list is a vector of unique alleles for the ith locus.

 $\verb|male.code| \qquad \qquad \text{The code denoting a male in the sex vector.}$ 

female.code The code denoting a female in the sex vector.

chrom.label Chromosome Label

#### **Side Effects**

#### References

#### Note

A matrix that contains all elements of mode character will be sorted in alphabetic order.

locus 43

#### See Also

locus, setupGeno

### **Examples**

```
# Create some loci to work with
a1 <- 1:6
a2 <- 7:12

b1 <- c("A", "A", "B", "C", "E", "D")
b2 <-c("A", "A", "C", "E", "F", "G")

c1 <- c("101", "10", "115", "132", "21", "112")
c2 <- c("100", "101", "0", "100", "21", "110")

myloci <- data.frame(a1,a2,b1,b2,c1,c2)
myloci <- loci(myloci, locus.names=c("A", "B", "C"), miss.val=c(0,NA))
myloci
attributes(myloci)</pre>
```

locus

Creates an object of class "locus"

### **Description**

Creates an object containing genotypes for multiple individuals. The object can then use method functions developed for objects of class "locus".

#### Usage

### **Arguments**

allele1	A vector containing the labels for 1 allele for a set of individuals, or optionally a matrix with 2 columns each containing an allele for each person.
allele2	A vector containing the labels for the second allele for a set of individuals. If allele 1 is a matrix, allele 2 need not be specified.
chrom.label	A label describing the chromosome the alleles belong to
locus.alias	A vector containing one or more aliases describing the locus. The first alias in the vector will be used as a label for printing in some functions such as multilocus.print().
x.linked	A logical value denoting whether the chromosome is x linked
sex	A vector containing the gender of each individual (required if x.linked=T)
male.code	The code denoting a male in the sex vector
female.code	The code denoting a female in the sex vector
miss.val	a vector of codes denoting missing values for allele1 and allele2. Note that NA will always be treated as a missing value, even if not specified in miss.val. Also note that if multiple missing value codes are specified, the original missing value code for a specific individual can not be retrieved from the locus object.

44 locus

### **Details**

#### Value

Returns an object of class locus which inherits from class model.matrix containing the following elements:

geno a matrix with 2 columns where each row contains numeric codes for the 2 alleles

for an individual.

chrom.label a chromosome label

locus.alias a vector of aliases for the locus

x.linked a logical value specifying if the locus is x-linked or not

allele.labels

a vector of labels corresponding to the numeric codes in matrix geno (similar to

levels in a factor)

male.code a code to be used to identify males for an x.linked locus.

female.code a code to be used to identify females for an x.linked locus.

#### **Side Effects**

48 plot.haplo.score

```
plot.haplo.score Plot Haplotype Frequencies versus Haplotype Score Statistics
```

#### **Description**

Method function to plot a class of type haplo.score

#### Usage

```
plot.haplo.score(x, ...)
```

#### **Arguments**

- x The object returned from haplo.score (which has class haplo.score).
- ... Dynamic parameter for the values of additional parameters for the plot method.

#### **Details**

This is a plot method function used to plot haplotype frequencies on the x-axis and haplotype-specific scores on the y-axis. Because haplo.score is a class, the generic plot function can be used, which in turn calls this plot.haplo.score function.

### Value

Nothing is returned.

### **Side Effects**

### References

Schaid DJ, Rowland CM, Tines DE, Jacobson RM, Poland GA. "Score tests for association of traits with haplotypes when linkage phase is ambiguous." Amer J Hum Genet. 70 (2002): 425-434.

### See Also

haplo.score

plot.haplo.score.slide 49

```
plot.haplo.score(score.gaus)
```

### **Description**

Method function to plot an object of class haplo.score.slide. The p-values from haplo.score.slide are for sub-haplotypes of a larger chromosomal region, and these are plotted to visualize the change in p-values as the sub-haplotype "slides" over a chromosome. Plot -log10(p-value) on the y-axis vs. the loci over which it was computed on the x-axis.

### Usage

#### **Arguments**

х	The object returned from haplo.score.slide
pval	Character string for the choice of p-value to plot. Options are: "global" (the global score statistic p-value based on an asymptotic chi-square distribution), "global.sim" (the global score statistic simulated p-value), and "max.sim" (the simulated p-value for the maximum score statistic).
dist.vec	Numeric vector for position (i.e. in cM) of the loci along a chromosome. Distances on x-axis will correspond to these positions.
cex	Character expansion size.
srt	String rotation in degrees measured counterclockwise from horizontal. Applies to x-axis (locus) labels.
	Dynamic parameter for the values of additional parameters for the plot method.

#### **Details**

The x-axis has tick marks for all loci. The y-axis is the  $-\log 10()$  of the selected p-value. For each haplo.score result, plot a horizontal line at the height of  $-\log 10(p$ -value) drawn across the loci over which it was calculated. Therefore a p-value of 0.001 for the first 3 loci will plot as a horizontal line plotted at y=3 covering the first three tick marks.

### Value

Nothing is returned.

### **Side Effects**

# Usage

```
print.haplo.score.slide(x, digits=max(options()$digits - 2, 5), ...)
```

# Arguments

х	A haplo.score.slide object
digits	Number of digits to print for numeric output
	Optional arguments for the print method

58 printBanner

printBanner

Print a nice banner

### **Description**

### Usage

```
printBanner(str, banner.width=options()$width, char.perline=.75*banner.width, bo
```

### **Arguments**

str character string - a title within the banner

banner.width

width of banner, the default is set to fit current options

char.perline

number of characters per line for the title, the default is 75% of the banner.width

parameter

border type of character for the border

### **Details**

This function prints a nice banner in both R and S-PLUS

Value

60 score.sim.control

score.sim.control Create the list of control parameters for simulations in haplo.score

### **Description**

In the call to haplo.score, the sim.control parameter is a list of parameters that control the simulations. This list is created by this function, score.sim.control, making it easy to change the default values.

### Usage

```
score.sim.control(p.threshold=0.25, min.sim=1000, max.sim=20000.,verbose=FALSE)
```

### **Arguments**

p.threshold	A paremeter used to determine p-value precision from Besag and Clifford (1991). For a p-value calculated after min.sim simulations, continue doing simulations until the p-value's sample standard error is less than p.threshold * p-value. The dafault value for p.threshold = 1/4 corresponds approximately to having a two-sided 95% confidence interval for the p-value with a width as wide as the p-value itself. Therefore, simulations are more precise for smaller p-values. Additionally, since simulations are stopped as soon as this criteria is met, p-values may be biased high.
min.sim	The minimum number of simulations to run. To run exactly min.sim simulations, set max.sim = min.sim. Also, if run-time is an issue, a lower minimum (e.g. 500) may be useful, especially when doing simulations in haplo.score.slide.
max.sim	The upper limit of simulations allowed. When the number of simulations reaches max.sim, p-values are approximated based on simulation results at that time.
verbose	Logical, if (T)rue, print updates from every simulation to the screen. If (F)alse, do not print these details.

#### Details

In simulations for haplo.score, employ the simulation p-value precision criteria of Besag and Clifford (1991). The criteria ensures both the global and the maximum score statistic simulated p-values be precise for small p-values. First, perform min.sim simulations to guarantee sufficient precision for the score statistics on individual haplotypes. Then continue simulations as needed until simulated p-values for both the global and max score statistics meet precision requirements set by p.threshold.

#### Value

A list of the control parameters:

p.threshold	As described above
min.sim	As described above.
max.sim	As described above
verbose	As described above

setupData 61

Besag, J and Clifford, P. "Sequential Monte Carlo p-values." Biometrika. 78, no. 2 (1991): 301-304.

### See Also

```
haplo.score
```

#### **Examples**

setupData

Set up an example dataset provided within the library.

### Description

This function defines an alias function to run exactly as data() in R and does nothing in Splus. R keeps a data set within the working data frame, so we only want to load data it when calling an example. Splus keeps it in the background, so it is already loaded upon library(mypkg).

### Usage

```
setupData(...)
```

#### **Arguments**

. . . The name of a dataset provided within the Splus/R library.

**Details** 

Value

**Side Effects** 

References

62 setupGeno

#### See Also

### **Examples**

```
## for a data set named my.data load it by
# setupData(my.data)

## check the names of my.data to see if it is loaded
# names(my.data)
```

setupGeno

Create a group of locus objects from a genotype matrix, assign to 'model.matrix' class.

#### **Description**

The function makes each pair of columns a locus object, which recodes alleles to numeric and saves the original alleles as an attribute of the model.matrix.

#### Usage

```
setupGeno(geno, miss.val=c(0,NA))
```

#### **Arguments**

geno

Matrix of alleles, such that each locus has a pair of adjacent columns of alleles, and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then ncol(geno) = 2\*K. Rows represent alleles for each subject.

miss.val

A vector of codes denoting missing values for allele1 and allele2. Note that NA will always be treated as a missing value, even if not specified in miss.val. Also note that if multiple missing value codes are specified, the original missing value code for a specific individual can not be retrieved from the loci object.

#### **Details**

#### Value

A 'model.matrix' object with the alleles recoded to numeric values, and the original values are stored in the 'unique.alleles' attribute. The ith item of the unique.alleles list is a vector of unique alleles for the ith locus.

#### **Side Effects**

#### References

summary.haplo.em 63

#### Note

A matrix that contains all elements of mode character will be sorted in alphabetic order.

#### See Also

locus, loci, haplo.glm

#### **Examples**

```
# Create some loci to work with
a1 <- 1:6
a2 <- 7:12
b1 <- c("A","A","B","C","E","D")
b2 <-c("A","A","C","E","F","G")
c1 <- c("101","10","115","132","21","112")
c2 <- c("100","101","0","100","21","110")
myGeno <- data.frame(a1,a2,b1,b2,c1,c2)
myGeno <- setupGeno(myGeno)
myGeno
attributes(myGeno)$unique.alleles</pre>
```

summary.haplo.em Summarize contents of a haplo.em object

### **Description**

Display haplotype pairs and their posterior probabilities by subject. Also display a table with number of max haplotype pairs for a subject versus how many were kept (max vs. used).

### Usage

```
summary.haplo.em(object, show.haplo=FALSE, nlines=NULL, ...)
```

# **Arguments**

```
object A haplo.em object
show.haplo Logical. If TRUE, show the alleles of the haplotype pairs, otherwise show only the recoded values.

nlines To shorten output, print the first 1:nlines rows of the large data frame.

Optional arguments for the summary method
```

### **Details**

#### Value

64 summaryGeno

#### Side Effects

#### References

#### See Also

haplo.em

#### **Examples**

summaryGeno

Summarize Full Haplotype Enumeration on Genotype Matrix

#### **Description**

Provide a summary of missing allele information for each individual in the genotype matrix. The number of loci missing zero, one, or two alleles is computed, as well as the total number of haplotype pairs that could result from the observed phenotype.

### Usage

```
summaryGeno(geno, miss.val=0)
```

### **Arguments**

geno Matrix of alleles, such that each locus has a pair of adjacent columns of alleles,

and the order of columns corresponds to the order of loci on a chromosome. If there are K loci, then geno has 2\*K columns. Rows represent all observed

alleles for each subject.

miss.val Vector of codes for allele missing values.

#### **Details**

After getting information on the individual loci, this function makes a call to geno.count.pairs(). The E-M steps to estimate haplotype frequencies considers haplotypes that could result from a phenotype with a missing allele. It will not remove a subject's phenotype, only the unlikely haplotypes that result from it.

#### Value

Data frame with columns representing the number of loci with zero, one, and two missing alleles, then the total haplotype pairs resulting from full enumeration of the phenotype.

#### **Side Effects**

varfunc.glm.fit 65
